Executive Summary

This document describes an example configuration of a performance-optimized Red Hat® Ceph® Storage (RHCS) cluster using Micron® NVMe™ SSDs, AMD EPYC™ 7002 x86 architecture-based rack-mount servers, and 100 Gb/E networking.

It details the hardware and software building blocks used to construct this reference architecture (including the Red Hat Enterprise Linux OS configuration, network switch configurations, and Ceph tuning parameters) and shows the performance test results and measurement techniques for a scalable 4-node RHCS architecture.

Optimized for block performance while also providing very high-performance object storage, this all-NVMe solution provides a rack-efficient design to enable:

Faster deployment: The configuration has been pre-validated, optimized, and documented to enable faster deployment and faster performance than using default instructions and configuration.

Balanced design: The right combination of NVMe SSDs, DRAM, processors, and networking ensures a balanced set of subsystems optimized for performance.

Broad use: Complete documentation of tuning and performance characterization across multiple IO profiles for broad deployment across multiple uses.

Our testing illustrates exceptional performance results for 4 KiB random block workloads and 4 MiB object workloads, as shown in Tables 1a and 1b.

4 KiB Random Block Performance			4 MiB Object Performance

Micron Reference Architectures

Micron Reference Architectures are optimized, pre-engineered, enterprise-leading solution templates for platforms that are co-developed between Micron and industry-leading hardware and software companies.

Designed and tested at Micron's Storage Solutions Center, they provide end users, system builders, independent software vendors (ISVs), and OEMs with a proven template to build next-generation solutions with reduced time investment and risk.

Why Micron for this Solution

Storage (SSDs and DRAM) represents a large portion of the value of today's advanced server/storage solutions. Micron's storage expertise starts at memory technology research, innovation, and design and extends to collaborating with customers and software providers on total data solutions. Micron develops and manufactures the storage and memory products that go into the enterprise solutions described here.

Ceph Distributed Architecture Overview

A Ceph storage cluster consists of multiple Ceph monitor nodes and data nodes for scalability, fault-tolerance, and performance. Ceph stores all data as objects, regardless of the client interface used. Each node is based on industry-standard hardware and uses intelligent Ceph daemons that communicate with each other to:

- Store, retrieve, and replicate data objects
- Monitor and report on cluster health
- Redistribute data objects dynamically
- Ensure data object integrity
- Detect and recover from faults and failures

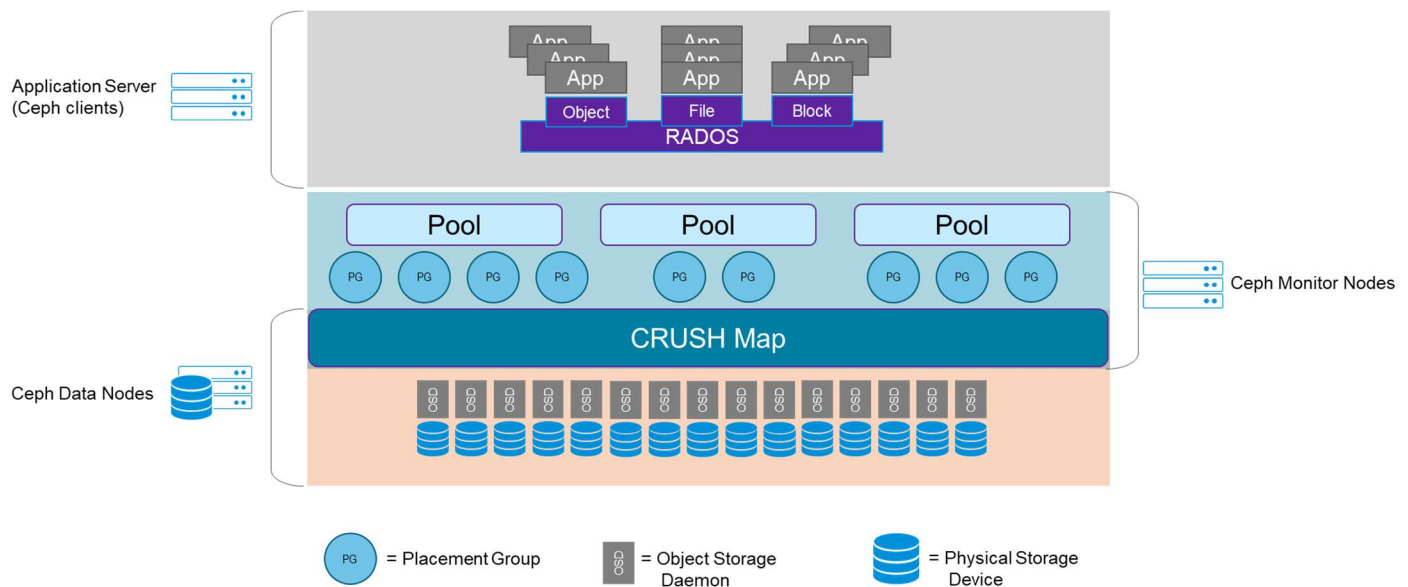

Figure 1 - Ceph Architecture

To the application servers (Ceph clients) that read and write data, a Ceph storage cluster looks like a simple pool storage resource for data; however, the storage cluster performs many complex operations in a manner that is completely transparent to the application server. Ceph clients and Ceph object storage daemons (Ceph OSDs or OSDs) both use the Controlled Replication Under Scalable Hashing (CRUSH) algorithm for storage and retrieval of objects.

For a Ceph client, the storage cluster is very simple. When a Ceph client reads or writes data (referred to as an IO context), it connects to a logical storage pool in the Ceph cluster. The figure above illustrates the overall Ceph architecture, with concepts described in the sections that follow.

Clients write to Ceph storage pools while the CRUSH ruleset determines how placement groups get distributed across OSDs.

Pools: Ceph clients store data objects in logical, dynamic partitions called pools. Administrators can create pools for various reasons such as for particular data types, to separate block, file and object usage, application isolation, or to separate user groups (multitenant hosting). The Ceph pool configuration dictates the number of object replicas and the number of placement groups (PGs) within the pool. Ceph storage pools can be either replicated or erasure-coded, as appropriate, for the application and cost model. Additionally, pools can “take root” at any position in the CRUSH hierarchy, allowing placement on groups of servers with differing performance characteristics, which allows for the optimization of different storage workloads.

Object storage daemons: Object storage daemons (OSDs) store data and handle data replication, recovery, backfilling, and rebalancing. They also provide some cluster state information to Ceph monitor nodes by checking other Ceph OSDs with a heartbeat mechanism. A Ceph storage cluster, configured to keep three replicas of every object, requires a minimum of three OSDs; two of which need to be operational to process write requests successfully. Ceph OSDs roughly correspond to a file system on a physical hard disk drive.

Placement groups: Placement groups (PGs) are shards, or fragments, of a logical object pool that are composed of a group of Ceph OSDs that are in a peering relationship. PGs provide a means of creating replication or erasure coding groups of coarser granularities than on a per-object basis. A larger number of placement groups (e.g., 200 per OSD or more) leads to better balancing.

CRUSH map: The CRUSH algorithm determines how to store and retrieve information from data nodes. CRUSH enables clients to communicate directly with OSDs on data nodes rather than through an intermediary service. By doing so, this removes a single point of failure from the cluster. The CRUSH map consists of a list of all OSDs and their physical location. Upon initial connection to a Ceph-hosted storage resource, the client contacts a Ceph monitor node for a copy of the CRUSH map, which enables direct communication between the client and the target OSDs.

Ceph monitors (MONs): Before Ceph clients can read or write data, they must contact a Ceph MON to obtain the current CRUSH map. A Ceph storage cluster can operate with a single MON, but this introduces a single point of failure. For added reliability and fault tolerance, Ceph supports an odd number of monitors in a quorum (typically three or five for small to mid-sized clusters). Consensus among various MON instances ensures consistent knowledge about the state of the cluster.

Reference Architecture Overview

Micron designed this reference architecture on the AMD EPYC 7002 architecture using dual AMD 7742 processors. This processor architecture provides a performance-optimized server platform while yielding an open, cost-effective software-defined storage (SDS) platform suitable for a wide variety of use cases such as OpenStack™ cloud, video distribution, transcoding, and big data storage.

AMD EPYC 7002 Processors: Utilizing the x86 architecture and built on 7nm technology, the AMD EPYC 7002 Series of processors bring together up to 64 cores, 4TB memory capacity, support for eight channels of DDR4-3200, and 128 lanes of PCIe® 4 IO, all with the right ratios to enable best-in-class video transcoding workloads. Optimize costs by choosing one socket or two sockets with the optimal core count needed to run your database without compromising on processor features.

The [Micron 7300 PRO NVMe SSD](#) offers excellent performance with lower power consumption and latencies. Capacity per rack unit (RU) is maximized with ten 7.68TB NVMe SSDs per 1U storage node. This reference architecture takes up six RUs consisting of one monitor node and four data nodes and one Ethernet switch. Using this reference architecture as a starting point, administrators can add additional data nodes 1RU and 76TB at a time.

Two Mellanox ConnectX®-5 100 Gb/E network cards per server handle data traffic— one for the client/public network traffic and a second for the internal Ceph replication network traffic. Mellanox ConnectX-4 50 Gb/E network cards are installed in both the clients and monitor nodes for connection to the storage networks.

Figure 2 – Micron Ceph Reference Architecture

Note: Micron performed all tests using a single monitor node. Production deployments should use at least three monitor nodes to provide adequate redundancy to the solution.

Software

This section details the software versions used in the reference architecture.

Red Hat Ceph Storage

Red Hat collaborates with the global open source Ceph community to develop new Ceph features, then packages changes into predictable, stable, enterprise-quality releases. Red Hat Ceph Storage uses the open-

source Ceph Luminous version 12.2, to which Red Hat was a leading code contributor. This reference architecture uses version 3.3 of Red Hat Ceph Storage.

As a self-healing, self-managing, unified storage platform with no single point of failure, Red Hat Ceph Storage decouples software from hardware to support block, object, and file storage services on standard x86 servers, using either HDDs and/or SSDs, significantly lowering the cost of storing enterprise data. [OpenStack®](#) also uses Red Hat Ceph Storage along with services, including Nova, Cinder, Manila, Glance, Keystone, and Swift, and it offers user-driven storage lifecycle management. Ceph is a highly tunable, extensible, and configurable architecture, well suited for archival, rich media, and cloud infrastructure environments.

Among many of its features, Red Hat Ceph Storage provides the following advantages to this reference architecture:

- Block storage integrated with OpenStack, Linux, and KVM hypervisor
- Data durability via erasure coding or replication
- Red Hat Ansible automation-based deployment
- Advanced monitoring and diagnostic information with an on-premise monitoring dashboard
- Availability of service-level agreement (SLA)-backed technical support
- Red Hat Enterprise Linux (included with subscription) and the backing of a global open source community

Red Hat Enterprise Linux

Enterprises in need of a high-performance operating system environment depend on Red Hat® Enterprise Linux® (RHEL) for scalable, fully supported, open-source solutions. Micron uses version 7.7 of Red Hat Enterprise Linux in this reference architecture due to its performance, reliability, and security, as well as its broad usage across many industries. Supported by leading hardware and software vendors, RHEL provides broad platform scalability (from workstations to servers to mainframes) and a consistent application environment across physical, virtual, and cloud deployments.

Software by Node Type

Table 2 below shows the software and version numbers used in the Ceph monitor and storage nodes.

Operating System	Red Hat Enterprise Linux	7.7
Storage Software	Red Hat Ceph Storage	3.3
NIC Driver	Mellanox® OFED Driver	4.7-1.0.0.0

Table 2 - Software Deployed on Ceph Data and Monitor Nodes

The software used on the load generation client is the same as that used on the Ceph data and monitor nodes. All block testing used the open-source FIO storage load generation tool, version 3.1.0, leveraging the `librbid` module.

Hardware by Node Type

Ceph Data Node

The Ceph data nodes in this RA host two or more OSDs per physical SSD. While this RA used a server product available for purchase from one vendor, this RA does not make any recommendations regarding any specific

server vendor or implementation, focusing on the overall solution architecture built around AMD EPYC 7002 processors and architecture.¹

Mellanox ConnectX-5 network controller offers dual ports of 10/25/50/100 Gb/s Ethernet connectivity and advanced offload capabilities while delivering high bandwidth, low latency, and high computation efficiency for high performance, data-intensive, and scalable HPC, cloud, data analytics, database, and storage platforms.

Table 3 provides the details for the server architecture used for this Ceph data node role.

Server Type	AMD x86 (dual-socket) 1U with PCIe Gen 3/4
CPU (x2)	AMD EPYC 7742 (64 cores, 2.25GHz base)
DRAM (x16)	Micron 32GB DDR4-2666 MT/s, 512GB total per node
NVMe (x10)	Micron 7300 PRO NVMe SSDs, 7.68TB each
SATA (OS)	Micron 2200 BOOT (NVMe)
Network	2x Mellanox ConnectX-5 100 Gb/E dual-port (MCX516A-CCAT)

Table 3 - Storage Node Hardware Details

Ceph Monitor Node

The Ceph monitor node in this RA is an AMD EPYC 7001 architecture server. As with the Ceph data node, this RA does not make any recommendations regarding any specific server vendor or implementation, focusing on the overall solution architecture built around AMD processors and architecture.

ConnectX-4 EN network controller offers dual ports of 10/25/50/100 Gb/s Ethernet connectivity and advanced offload capabilities while delivering high bandwidth, low latency, and high computation efficiency for high performance, data-intensive, and scalable HPC, cloud, data analytics, database, and storage platforms.

Table 4 below provides the details for the server architecture used for this Ceph monitor node role.

Server Type	AMD x86 (single-socket) 1U with PCIe Gen3
CPU (x1)	1x AMD EPYC 7551P (32 cores, 2.0 GHz base)
DRAM (x8)	Micron 32GB DDR4-2400 MT/s, 256GB total per node
SATA (OS)	64GB SATA Disk on Motherboard
Network	1x Mellanox ConnectX-4 50 Gb/E single-port (MC4X413A-GCAT)

Table 4 -Monitor Node Hardware Details

¹ 2nd Gen AMD EPYC processors used on motherboards designed for the 1st Gen AMD EPYC processor require a BIOS update from the server manufacturer. The EPYC 7742, 7642 and 7542 are 225w parts and require additional updates. Contact the server manufacturer for support. For PCIe® 4 and DDR4-3200 memory support, contact the server manufacturer. A motherboard designed for 2nd Gen EPYC processors is required to enable all available functionality. ROM-06a

Micron Components Used

Micron 7300 PRO NVMe SSDs

This RA uses the 7300 PRO 7.68TB NVMe SSD. The Micron 7300 series of NVMe SSDs is Micron's inaugural entry in the mainstream NVMe SSD segment. Built upon the proven 96-layer NAND technology and the latest NVMe architecture, the 7300 provides up to 6X the performance of SATA at a reasonable cost. Available in both U.2 (7mm) and M.2 (80mm, 110mm) form factors and capacities ranging from 400MB to 7.68TB, the 7300 is the right SSD for a wide range of uses, including server boot, caching, database, and emerging applications.

Table 5 below summarizes the 7300 PRO 7.68TB specifications.

Model	7300 PRO	Interface	PCIe Gen3 x4
Form Factor	U.2	Capacity	7.68TB
NAND	Micron 3D TLC	MTTF	2M device hours
Sequential Read	3.0 GB/s	Random Read	520,000 IOPS
Sequential Write	1.8 GB/s	Random Write	85,000 IOPS
Endurance	22.4PB	Status	Production

Note: GB/s measured using 128K transfers, IOPS measured using 4K transfers. All data is steady state. Complete MTTF information can be provided by your Micron sales associate.

Table 5 - 7300 PRO 7.68TB Specifications Summary

Network Switches

This RA uses one 100 Gb/E switch (32x QSFP28 ports each). For production purposes, Micron recommends using two switches for redundancy purposes, with each switch partitioned to support two network segments — one for the client data transfer and the second for the Ceph intercluster storage network. Switches used in this RA use the Broadcom Tomahawk® switch architecture (Table 6).

Model	Supermicro SSE-C3632SR
Software	Cumulus™ Linux 3.4.2

Table 6 - Network Switches (Hardware and Software)

The [SSE-C3632S Layer 2/3 Ethernet Switch](#) provides an open networking-compliant solution, providing the ability to maximize the efficient and flexible use of valuable data center resources while providing an ideal platform for managing and maintaining those resources in a manner in tune with the needs of an organization.

Planning Considerations

The following topics provide information to enhance the overall experience of the solution and ensure the solution is scalable while maximizing performance.

Number of Ceph Storage Nodes

At least three (3) storage nodes must be present in a Ceph cluster to become eligible for Red Hat technical support. While this RA uses four data nodes, additional nodes can provide scalability and redundancy. Four (4) storage nodes represent a suitable starting point as a building block for scaling up to larger deployments.

Number of Ceph Monitor Nodes

A Ceph storage cluster deployed for production workloads should have at least three (3) monitor nodes on separate hardware for added resiliency. These nodes do not require high-performance CPUs. They do benefit from having SSDs to store the monitor map data. For testing purposes, this solution uses a single monitor node..

Replication Factor

NVMe SSDs have high reliability, with high MTTF and low bit error rate. Micron recommends using a minimum replication factor of two in production when deploying OSDs on NVMe versus a replication factor of three, which is common with legacy HDD-based storage.

CPU Sizing

Ceph OSD processes can consume large amounts of CPU while doing small block operations. Consequently, a higher CPU core count results in higher performance for I/O-intensive workloads.

For throughput-intensive workloads characterized by large sequential object-based I/O, Ceph performance is more likely to be bound by the maximum network bandwidth of the cluster. CPU sizing is less impactful.

Ceph Configuration Tuning

Tuning Ceph for NVMe devices can be complex. The ceph.conf settings used in this reference architecture optimize the solution for small block random performance (see Appendix A).

Networking

A 25 Gb/E network enables the solution to leverage the maximum block performance benefits of a NVMe-based Ceph cluster. For throughput-intensive workloads, Micron recommends 50 Gb/E or faster throughput connections.

OS Tuning/NUMA

This RA used Ceph-Ansible for OS tuning and applied the following OS settings:

```
disable_transparent_hugepage: true
kernel.pid_max, value: 4,194,303
fs.file-max, value: 26,234,859
vm.zone_reclaim_mode, value: 0
vm.swappiness, value: 1
vm.min_free_kbytes, value: 1,000,000
net.core.rmem_max, value: 268,435,456
net.core.wmem_max, value: 268,435,456
net.ipv4.tcp_rmem, value: 4096 87,380 134,217,728
net.ipv4.tcp_wmem, value: 4096 65,536 134,217,728
ceph_tcmalloc_max_total_thread_cache: 134,217,728
```

Due to the unbalanced nature of the servers concerning PCIe lane assignments (four NVMe devices and both NICs attach to CPU 1, while the other six NVMe devices attach CPU 2), this RA did not use any NUMA tuning during testing.

`Irqbalance` was active for all tests and did a reasonable job balancing across CPUs.

Measuring Performance

4 KiB Random Workloads

Small block testing used the FIO synthetic I/O generation tool and the Ceph RADOS Block Device (RBD) driver to generate 4 KiB random I/O workloads.

The test configuration consisted of initially creating 130 RBD images, resulting in each RBD image size of 75GB and a total of 9.75TB of data. Implementing a 2x replicated pool resulted in 19.5TB of total data stored within the cluster.

The four data nodes have a combined total of 2TB of DRAM (512GB per server), which is 10.2% of the dataset size.

Random write tests scaled the number of FIO clients running against the Ceph cluster at a fixed queue depth of 32. (A client is a single instance of FIO running on a load generation server.) Using a queue depth of 32 simulates an active RDB image consumer and allows tests to scale up to a high client count. The number of clients scale from 10 clients to 130 clients. The test used 10 load generation servers with an equal number of FIO instances on each load generation server.

Random reads and 70/30 read/write tests all used 130 FIO clients and their associated RBD images, scaling the queue depth per FIO client from 1 to 32 in base-2 increments. It is important to use all 130 FIO clients for these tests to ensure that tests access the entire 19.5TB dataset; otherwise, Linux filesystem caching can skew results, resulting in a false report of higher performance.

Three test iterations executed for 10 minutes, with a 2-minute ramp-up time, for a total of 12-minute per test iteration or 36 minutes per pass. Before each iteration, the test script clears all Linux filesystem caches. The results reported are the mathematical average across all test runs.

4MB Object Workloads

Object testing utilizes the RADOS Bench tool provided as part of the Ceph package to measure object I/O performance. This benchmark reports throughput performance in GiB/s and represents the best-case object performance. Object I/O uses a RADOS gateway service operating on each load generation server. The configuration of RADOS gateway is beyond the scope of this RA.

To measure object write throughput, each test executed RADOS Bench with a “threads” value of 16 on a load generation server writing directly to a Ceph storage pool using 4MB objects. RADOS Bench executed on a varying number of load generation servers scaled between 2 to 20 in base-2 increments.

To measure object read throughput, 10 RADOS Bench instances executed 4MB object reads against the storage pool while scaling RADOS Bench thread count between one thread and 32 threads in base-2 increments.

Five test iterations executed for 10 minutes. Before each iteration, the test script cleared all Linux filesystem caches. The results reported are the mathematical average across all test runs.

Baseline Performance Test Methodology

Storage and network performance is baseline tested without Ceph software to determine the theoretical hardware performance maximums using FIO (storage) and iPerf (network) benchmark tools. Each storage test executes one locally run FIO instance per NVMe drive (10 total NVMe drives) simultaneously. Each network test executes four concurrent iperf3 instances from each data node and monitor node to each other and from each client to each data server. The results represent the expected maximum performance possible using the specific server and network components in the test environment.

10 Micron 7300 PRO
SSDs deliver 1.1 million
4 KiB random read IOPS
and 880,000 4 KiB
random write IOPS in
baseline FIO testing on a
single storage server.

Storage Baseline Results

The baseline block storage test executed FIO across all 10 7300 PRO NVMe SSDs on each storage node. FIO instances executed 4 KiB random writes at a queue depth of 64 per FIO instance. Table 7 provides the average IOPS and latency for all storage baseline testing.

Storage Node	Write IOPS	Write Avg. Latency	Read IOPS	Read Avg. Latency
Node 1	893,225	2.93ms	1,185,665	2.18ms
Node 2	879,912	2.97ms	1,156,447	2.24ms
Node 3	860,289	3.06ms	1,169,932	2.25ms
Node 4	884,130	2.99ms	1,155,963	2.29ms

Table 7 - Baseline FIO 4 KiB Random Workloads

The baseline object storage test executed FIO across all 10 7300 PRO NVMe SSDs on each node. FIO instances executed 128 KiB sequential writes at a queue depth of eight per FIO instance. FIO instances executed 4 MiB sequential reads at a queue depth of eight per FIO instance. Table 8 provides the average throughput and latency results.

Storage Node	Write Throughput	Write Avg. Latency	Read Throughput	Read Avg. Latency
Node 1	10.776 GiB/s	14.53ms	14.059 GiB/s	11.11ms
Node 2	11.257 GiB/s	13.92ms	14.413 GiB/s	10.84ms
Node 3	10.133 GiB/s	15.45ms	13.165 GiB/s	11.86ms
Node 4	10.521 GiB/s	14.90ms	13.234 GiB/s	11.80ms

Table 8 - Baseline FIO 128 KiB Sequential Workloads

Network Baseline Results

Network connectivity tests used six concurrent iPerf3 instances running for one minute. Each iPerf3 instance on each server transmitted data to all other servers.

All storage nodes with 100 GbE NICs averaged 96+ Gb/s during testing. Monitor nodes and clients with 50 GbE NICs averaged 45+ Gb/s during testing.

Ceph Performance Results and Analysis

The results detailed below are based on a 2x replicated storage pool using version 3.3 of Red Hat Ceph Storage with 8192 placement groups.

Tests used 130 RBD images at 75GB each, providing 9.75TB of data on a 2x replicated pool (19.5TB of total data). Random write tests used a constant queue depth of 32, increasing the number of simultaneous clients from 10 to 130 in increments of 10. A queue depth of 32 simulated a reasonably active RDB image consumer and enabled tests to scale to a high number of clients.

Random read and 70/30 R/W tests executed an I/O load against all 130 RBD images, scaling up the queue depth per client from 1 to 32 in base-2 increments. Using 130 clients for every test ensured that Ceph used the Linux filesystem cache equally on all tests.

For each I/O workload described below, five 10-minute tests executed with a five-minute ramp-up time for each test. The results reported in the sections below is the mathematical average of each five-test pass.

Small Block Random Workload Testing

The following sections describe the resulting performance measured for random 4 KiB (4.0 x 210 byte) block read, write, and mixed read/write I/O tests.

4 KiB 100% Random Write Workloads

Write performance reached a maximum of 577K 4 KiB IOPS. Average latency showed a linear increase as the number of clients increased, reaching a maximum average latency of 10.59ms at 190 clients. Tail (99.99%) latency increased smoothly across the entire 200 clients tested, reaching a maximum of 475.8ms at 200 clients (Figure 3).

Figure 3 – 4 KiB Random Write IOPS vs. Latency

Ceph data nodes depend heavily on CPU for performance. Low client load shows CPU utilization starting at 50% with 10 clients and increasing steadily to over 66% at a load of 190 clients (Figure 4).

Figure 4 – 4 KiB Random Write IOPS vs. CPU Utilization

Table 9 summarizes the solution's write performance. Based on the observed behavior, write-centric small-block workloads should focus on sizing for no more than 85% CPU utilization. The actual number of clients attained before reaching this level of utilization depends on the CPU model chosen. This RA's choice of an AMD EPYC 7742 CPU indicates this solution can scale to 200 clients.

FIO Clients	IOPS	Average Latency	95% Latency	99.99% Latency	Average CPU Utilization
10 Clients	319,569	1.00ms	1.22ms	85.25ms	38.58%
20 Clients	431,395	1.48ms	4.45ms	103.38ms	50.73%
30 Clients	473,962	2.03ms	6.98ms	135.14ms	55.06%
40 Clients	499,710	2.57ms	8.98ms	159.11ms	57.56%
50 Clients	517,595	3.10ms	10.90ms	174.66ms	59.35%
60 Clients	532,444	3.62ms	12.81ms	194.75ms	60.84%
70 Clients	542,822	4.15ms	14.82ms	208.36ms	61.83%
80 Clients	551,303	4.67ms	16.86ms	222.67ms	62.73%
90 Clients	548,208	5.30ms	20.10ms	242.65ms	62.57%
100 Clients	548,275	5.89ms	23.69ms	265.03ms	62.74%
110 Clients	558,373	6.34ms	25.15ms	268.90ms	64.11%
120 Clients	555,093	6.97ms	29.74ms	291.73ms	64.00%
130 Clients	547,958	7.66ms	35.09ms	314.67ms	63.89%
140 Clients	552,283	8.18ms	37.95ms	315.92ms	64.33%
150 Clients	564,318	8.56ms	40.26ms	315.62ms	65.52%
160 Clients	561,645	9.18ms	44.09ms	341.04ms	65.50%
170 Clients	565,150	9.69ms	46.96ms	347.60ms	65.96%
180 Clients	561,560	10.35ms	52.06ms	378.22ms	65.64%
190 Clients	577,622	10.59ms	51.33ms	416.40ms	66.94%
200 Clients	577,459	11.15ms	55.04ms	475.80ms	66.23%

Table 9 – 4 KiB Random Write Results Summary

4 KiB Random Read Workload Analysis

Read performance of 130 FIO clients reached a maximum of 2.97 million 4 KiB IOPS. Average latency showed an increase as the queue depth increased, reaching a maximum average latency of only 1.4ms at queue depth 32. Average latency doubles moving from queue depth 16 to queue depth 32 while generating the same IOPS performance. Tail (99.99%) latency increased steadily up to a queue depth of 8, then spiked upward at queue depth of 16 (16% increase) and then again at queue depth of 32, going from 60.45ms at queue depth 16 to 324ms at queue depth 32 — an increase of over 435% (Figure 5).

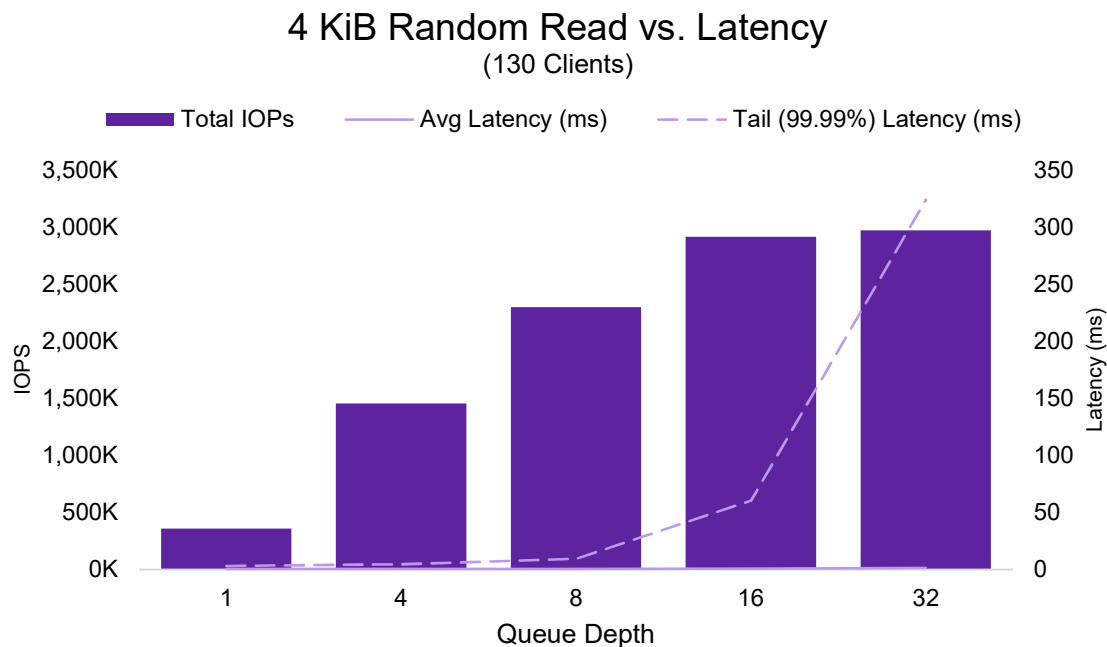

Figure 5 - 4 KiB Random Read IOPS vs. Latency

Low queue depth showed CPU utilization starting at 14.5% at queue depth of 1 and increasing steadily to over 78% at a queue depth of 32 (Figure 6).

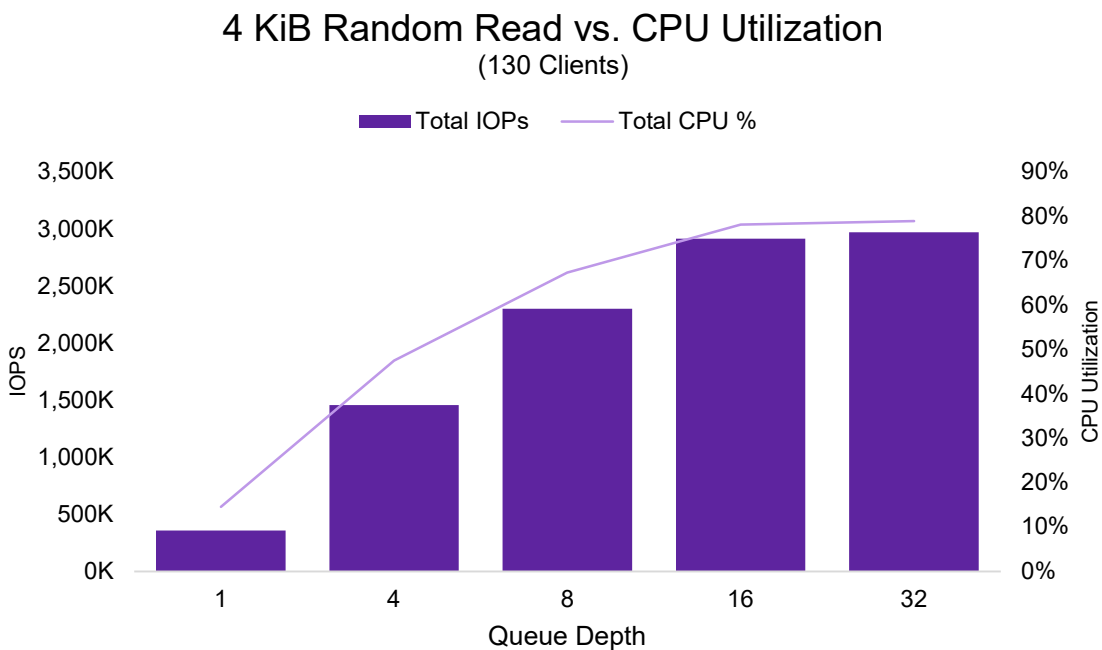

Figure 6 – 4 KiB Random Read IOPS vs. CPU Utilization

Table 10 summarizes the solution's read performance. Based on the observed behavior, read-centric small-block workloads should focus on sizing for no more than 80% CPU utilization. The actual queue depth and client load attained before reaching this level of utilization will depend on the CPU model chosen. This RA's choice of an AMD EPYC 7742 CPU indicates the target sizing should be queue depth 16 for most use cases, as moving to queue depth 32 provides no additional IOPS performance while incurring a heavier latency penalty.

FIO Clients	IOPS	Average Latency	95% Latency	99.99% Latency	Average CPU Utilization
QD 1	357,398	0.36ms	0.44ms	3.06ms	14.54%
QD 4	1,454,804	0.35ms	0.47ms	4.57ms	47.48%
QD 8	2,299,279	0.45ms	0.66ms	9.43ms	67.28%
QD 16	2,915,255	0.71ms	1.18ms	60.45ms	78.14%
QD 32	2,970,481	1.42ms	1.37ms	324.06ms	78.93%

Table 10 – 4 KiB Random Read Results Summary

4 KiB Random 70% Read/30% Write Workload Analysis

Mixed read and write (70% read/30% write) performance of 130 FIO clients reached a maximum of 1.29 million 4 KiB IOPS. Both read and write average latency showed an increase as the queue depth increased, reaching a maximum average read latency of 2.08ms and a maximum average write latency of 5.89ms at queue depth 32.

Tail (99.99%) latency for both reads and writes increased rapidly as queue depth increased with read latency, going from 6.80ms at queue depth 1 to 311ms at queue depth 32 and with write latency increasing from 11.76ms at queue depth 1 to 365.3ms at queue depth 32 (Figure 7).

Figure 7 - 4 KiB Random 70/30 Read/Write IOPS vs. Latency

Low queue depth shows CPU utilization starting at 19.6% and increasing steadily to over 79.2% at queue depth 32 (Figure 8).

Figure 8 – 4 KiB Random 70/30 Read/Write IOPS vs. CPU Utilization

Table 11 summarizes the solution's 70%/30% read/write performance. Based on the observed behavior, mixed I/O small-block workloads should level out at around 80% CPU utilization. The actual queue depth and client load attained before reaching this level of utilization will depend on the CPU model chosen and the actual read/write ratio. This RA's choice of an AMD EPYC 7742 processor and 70%/30% read/write mix indicates the target sizing should be a queue depth of 16 due to the 32% (read) and 29% (write) increase in latency for an I/O performance gain of 13%.

FIO Clients	IOPS	Avg Write Latency (ms)	Avg Read Latency (ms)	99.99% Write Latency	99.99% Read Latency	Avg. CPU Utilization
QD 1	250,034	0.76ms	0.41ms	11.76ms	6.80ms	19.64%
QD 4	707,067	1.18ms	0.54ms	167.29ms	102.26ms	50.99%
QD 8	938,054	1.90ms	0.76ms	217.93ms	159.92ms	64.64%
QD 16	1,135,643	3.28ms	1.20ms	282.94ms	234.33ms	73.14%
QD 32	1,289,009	5.89ms	2.08ms	365.36ms	311.35ms	79.21%

Table 11 - 4 KiB Random 70/30 Read/Write Results Summary

4 MiB Object Workloads

The following sections describe the resulting performance measured for random, 4 MiB (4.0×2^{20} byte) object read and write data in both sequential (read and write) and random (reads only) IO scenarios.

Write tests measure performance using RADOS Bench workload instances consisting of a constant 16 threads per instance. The test increases load by instantiating additional RADOS Bench instances from two to 20 in base-2 increments.

Read tests executed measure performance by executing a fixed 10 RADOS Bench workload instance while increasing the number of threads from 4 to 32 in base-2 increments.

Object Write Workload Analysis

Object write performance reached a maximum throughput of 21 GiB/s with an average latency of 57.6ms at a workload level of 20 instances. Latency growth was consistent as the workload increased to 10 instances, with a spike to 57ms at 20 instances — a 67% increase — while overall throughput increased by 15% (Figure 9).

Figure 9 – 4 MiB Object Write Throughput vs. Average Latency

CPU utilization was extremely low for this test, indicating it may be possible to scope a lower power CPU for large-block, object-based use cases. Average CPU utilization for this RA never reached higher than 10% (Figure 10).

Figure 10 – 4 MiB Object Write Throughput vs. Average CPU Utilization

Table 12 summarizes the solution's object write performance. Based on the observed behavior, write-centric object workloads should focus on maximizing throughput by adding additional network interfaces as server PCIe architecture permits. The actual queue depth and client load attained before reaching this level of throughput depends on the CPU model chosen. This RA's choice of an AMD EPYC 7742 CPU indicates the target sizing should be in the range of 160 to 320 total threads for optimal performance.

Clients	Write Throughput	Average Latency	Average CPU Utilization
2 Instances	9.48 GiB/S	13.44ms	3.50%
4 Instances	13.71 GiB/S	18.75ms	5.22%
6 Instances	16.00 GiB/S	23.96ms	6.26%
8 Instances	17.05 GiB/S	29.76ms	6.79%
10 Instances	18.20 GiB/S	34.74ms	7.36%
20 Instances	21.80 GiB/S	57.59ms	9.53%

Table 12 - 4 MiB Object Write Results Summary

Object Read Workload Analysis

Object read performance reached a maximum sequential throughput of 41 GiB/s – 85% of the aggregated available bandwidth of the four-node cluster – with an average latency of 29.7ms attained at 32 threads, while maximum random throughput achieved 43.7 GB/s – 91% of the aggregated available bandwidth of the four-node cluster – with an average latency of 27.9ms at 32 threads. Latency growth was consistent as workload increased, indicating that there were no apparent cases of resource constraints (Figure 11).

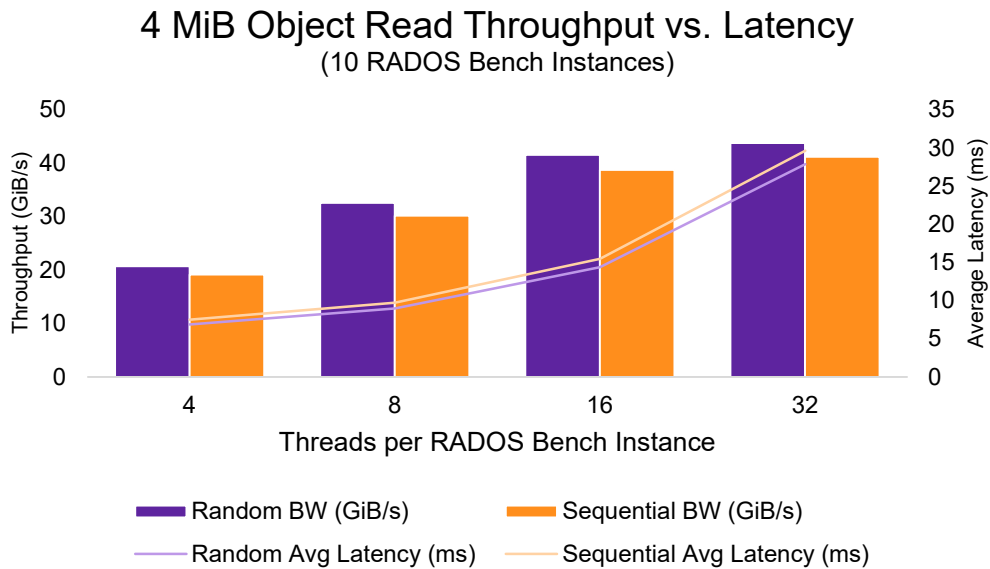

Figure 11 – 4 MiB Object Read Throughput vs. Average Latency

CPU utilization was extremely low for this test. Average CPU utilization for this RA never exceeded 14% (Figure 12).

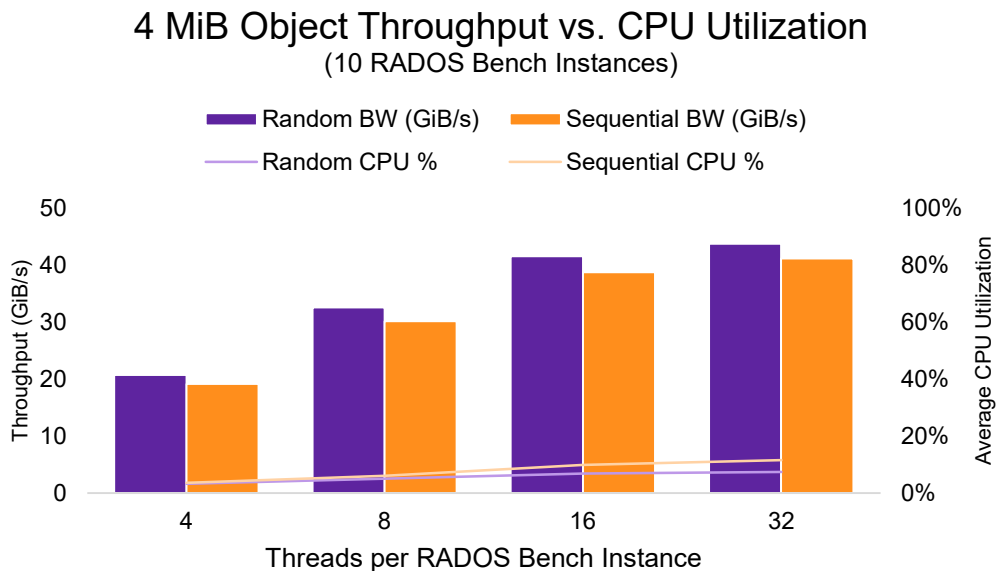

Figure 12 – 4 MiB Object Read Throughput vs. Average CPU Utilization

Table 13 summarizes the solution's object read performance. Based on the observed behavior, read-centric object workloads should focus on maximizing throughput. The actual queue depth and client load attained before reaching this level of throughput depends on the CPU model chosen. This RA's choice of an AMD EPYC 7742 CPU indicates the target sizing should be in the range of 320 total threads for optimal performance. More threads may provide additional performance, but is beyond the scope of testing performed in this RA.

Threads per Instance	Throughput	Random		Throughput	Sequential	
		Average Latency	Average CPU%		Average Latency	Average CPU%
4	20.74 GiB/s	6.89ms	3.24%	19.13 GiB/s	7.53ms	3.56%
8	32.59 GiB/s	8.94ms	4.99%	30.16 GiB/s	9.71ms	6.06%
16	41.56 GiB/s	14.38ms	6.83%	38.77 GiB/s	15.45ms	9.81%
32	43.77 GiB/s	27.91ms	7.46%	41.22 GiB/s	29.67ms	11.59%

Table 13 – 4 MiB Object Read Results Summary

Summary

Micron designed this reference architecture for small-block random workloads. With over 2.97 million 4 KiB random reads and 558,000 4 KiB random writes in a compact design based on four 1RU data nodes and one or more 1RU monitor nodes and 307GB of total storage, this solution is a cost-effective, high-performance storage solution suitable for a wide variety of application use cases.

While optimized for small-block workloads, this Ceph solution demonstrated excellent object performance as well as offering aggregated throughput of up to 90% of the available network bandwidth. Taking typical TCP/IP overhead into consideration, this solution, as configured, fully utilized the available throughput for large-block workloads. Additional network interfaces installed in each storage node may support increased Ceph object throughput, though this hypothesis was not tested.

Micron's enterprise NVMe SSDs enable massive performance and provide a suitable solution for many different types of storage solutions, such as Red Hat Ceph Storage software-defined storage area networks. Whether you need to support general purpose use cases or you require ultra-fast responses for transactional workloads or large, fast data analytics solutions, Micron has taken the guesswork out of building the right solution.

About Micron

Micron Technology (Nasdaq: MU) is a world leader in innovative memory solutions. Through our global brands — Micron, Crucial® and Ballistix® — our broad portfolio of high-performance memory technologies, including DRAM, NAND, NOR Flash and 3D XPoint™ memory, is transforming how the world uses information to enrich life. Backed by 40 years of technology leadership, our memory and storage solutions enable disruptive trends, including artificial intelligence, 5G, machine learning and autonomous vehicles, in key market segments like data center, networking, automotive, industrial, mobile, graphics and client. Our common stock trades on the Nasdaq under the symbol MU.

About Red Hat

Red Hat is the world's leading provider of open source software solutions, using a community-powered approach to provide reliable and high-performing cloud, Linux, middleware, storage, and virtualization technologies. Red Hat also offers award-winning support, training, and consulting services. As a connective hub in a global network of enterprises, partners, and open source communities, Red Hat helps create relevant, innovative technologies that liberate resources for growth and prepare customers for the future of IT.

About Ceph Storage

Ceph is an open source distributed object store and file system designed to provide excellent performance, reliability, and scalability. It can:

- Free you from the expensive lock-in of proprietary, hardware-based storage solutions.
- Consolidate labor and storage costs into one versatile solution.
- Introduce cost-effective scalability on self-healing clusters based on standard servers and disks

Benchmark software and workloads used in performance tests may have been optimized for performance on specified components and have been documented here where possible. Performance tests, such as HClbench, are measured using specific computer systems, components, software, operations and functions. Any change to any of those factors may cause the results to vary. You should consult other information and performance tests to assist you in fully evaluating your contemplated purchases, including the performance of that product when combined with other products.
